Description	
Hi,	
I understand why the TS option config.prefixLocalAnchors is useful to prefix all local anchors with the relative path, but all GET parameters are prepended as well.	
I do not think this is desired so it might be a bug.	
Example:	
Calling e.g. http://somehost.org/?test=abc results in local anchors like <code>...</code>

As far as I know this is not a bug. The feature prefixes the current url to the anchor. How should the Core know which parameters have to be removed and which need to be kept?

Agreed, this is not a bug. This is how prefixLocalAchers works.

The only mitigation here is not use basURL at all and also not prefixLocalAchers, but just absRefPrefix
